In this work, we present an investigation of the optical properties and band structure calculations for the photonic crystal structures (PCs) based on one-dimensional (1D) photonic crystal. Here we use 1D $A^5B^6C^7$ (A:Sb; B:S,Se; C:I) based layers in air background. We have theoretically calculated photonic band structure and optical properties of $A^5B^6C^7$ (A:Sb; B:S,Se; C:I) based PCs. In our simulation, we employed the finite-difference time domain (FDTD) technique and the plane wave expansion method (PWE) which implies the solution of Maxwell equations with centered finite-difference expressions for the space and time derivatives.

1 Introduction It is well known that the photonic crystal (PC) based superlattices can play an essential role in controlling of the optical processes in various devices of optoelectronics [1]. Therefore, great attention is paid to the investigation of physical properties of PC based superlattices. The PC based superlattices of various types are considered, namely, strictly periodic, disordered, lattices with defects, etc. The structures intermediate between the periodic and disordered structures, or quasi-periodic lattices – the Fibonacci and Thue-Morse superlattices, occupy a special place among the superlattices.

On the other hand, one of the topics of interest in optics of PC is the possibility to taylor emittance/absorptance by changing the distribution of electromagnetic modes. Emittance tayloring by conventional PCs was investigated in [2, 3]. One of the structures that may be used in emittance tayloring are quasiperiodic multilayers, likes the Fibonacci superlattices [4]. Due to their structural self-similarity, these show regularities in their transmission/reflection spectra. The strong resonances in spectral dependences of fractal multilayers can localize light very effectively [1, 5]. Also, long-range ordered aperiodic photonic structures offer a large flexibility for the design of optimized light emitting devices, the theoretical understanding of the complex mechanisms governing optical gaps and mode formation in aperiodic structures becomes increasingly more important. The formation of photonic band gaps and the existence of quasi-localized light states have already been demonstrated for one (1D) and two-dimensional (2D) aperiodic structures based on Fibonacci and the Thue-Morse sequences [1, 4]. However, to the best of our knowledge, a rigorous investigation of the band gaps and optical properties in more complex types of aperiodic structures has not been reported so far.

In this paper, we investigated the energy spectrum and optical properties in the Fibonacci-type photonic band gap (PBG) structures consisting of ferroelectric materials ($A^5B^6C^7$) in detail by using FDTD and PWE methods.

2 Model and method

2.1 Fibonacci sequences and model Quasiperiodic structures are nonperiodic structures that are constructed by a simple deterministic generation rule. In a quasiperiodic system two or more incommensurate periods

are superimposed, so that it is neither aperiodic nor a random system and therefore can be considered as intermediate the two [1]. In other words due to a long-range order a quasiperiodic system can form forbidden frequency regions called pseudo band gaps similar to the band gaps of a PC and simultaneously possess localized states as in disordered media [5]. The Fibonacci multilayer structure (well-known quasiperiodic structure) has been studied in past decade, and recently the resonant states at the band edge of the photonic structure in the Fibonacci sequence are studied experimentally, too [6]. A 1D quasi-periodic Fibonacci sequence is based on a recursive relation, which has the form, $S_{j+1}=\{S_{j-1}, S_j\}$ for $j\geqslant 1$, with $S_0=\{B\}$, $S_1=\{A\}$, $S_2=\{BA\}$, $S_3=\{ABA\}$, $S_4=\{BAABA\}$ and so on, where S_j is a structure obtained after j iterations of the generation rule. Here A and B are defined as being two dielectric materials, with different refractive indices (n_A, n_B) and have geometrical layer thickness (d_A, d_B). In place of materials A and B, we used air (A) and anisotropic antimony sulfoiodide and antimony selenium iodide (B;SbSI, SbSeI) respectively [7]. In Fig. 1 and 2 we show schematically the geometry of conventional PCs and Fibonacci PCs. 1D photonic crystals are characterized by the refractive index contrast and filling fraction. The refractive index contrast is the ratio of the higher refractive index to the lower refractive index in the multiplexer system. The filling fraction f is the ratio between the thickness of the lower refractive index layer(air) and the period of the PC, i.e., $f=d_1/(d_1+d_2)$. A typical 1D PCs and Fibonacci PCs are shown in Fig. 1 and Fig. 2.

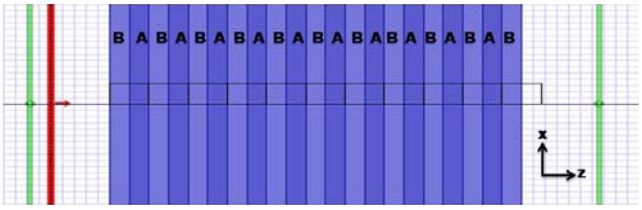

Figure 1 1-dimensional SbSI based photonic crystal structure (PCs).

Figure 2 1-dimensional SbSI based Fibonacci photonic crystal structure (FPCs).

The refractive index contrasts of SbSI are taken as follows: $n_a=2.87$ $n_b=3.63$ $n_c=4.55$ $T_c=22$ ºC (paraelectric phase) $n_a=2.87$ $n_b=3.57$ $n_c=4.44$ $T_c\approx 12$ ºC (ferroelectric phase) at $\lambda=633$ nm.

The refractive index of the background dielectric medium is assumed as air ($n_{air}=1.0$).

2.2 Finite difference time domain (FDTD) method and plane wave expansion method (PWE)

In our calculations, we used OptiFDTD software package [8]. The OptiFDTD software package is based on the finite-difference time-domain (FDTD) method for transmission spectra and the plane wave expansion method (PWE) for photonic band structure.

The photonic band structures of the proposed PCs were calculated by solving the Maxwell equations. The Maxwell equation in a transparent, time-invariant, source free, and non-magnetic medium can be written in the following form:

$$\nabla\times\frac{1}{\varepsilon(\mathbf{r})}\nabla\times\mathbf{H}(\mathbf{r})=\frac{\omega^2}{c^2}\mathbf{H}(\mathbf{r}) \quad (1)$$

where $\varepsilon(\mathbf{r})$ is the space dependent dielectric function, and c is the speed of light in vacuum. $\mathbf{H}(\mathbf{r})$ is the magnetic field vector of frequency ω and time dependence $e^{j\omega t}$.

This equation is sometimes called the Master Equation, and represents an Hermitian eigenproblem, which would not be applicable if the wave equation were derived in terms of the electric field. The Bloch theorem states that, due to infinite periodicity, the magnetic field will take the form

$$\mathbf{H}(\mathbf{r})=e^{jkr}h_k(\mathbf{r}) \quad (2)$$

where

$$\mathbf{h}_k(\mathbf{r})=h_k(\mathbf{r}+\mathbf{R}) \quad (3)$$

for all combinations of lattice vectors ***R***. Thus, Maxwell equation is given in operator form:

$$(\nabla\times j\mathbf{k})\times\left[\frac{1}{\varepsilon(\mathbf{r})}(\nabla\times jk)\right]\times\mathbf{h}_k=\frac{\omega^2}{c^2}\mathbf{h}_k \quad (4)$$

By solving these equations for the irreducible Brillouin zone, we can obtain the photonic band structure.

FDTD algorithm is one of the most appropriate calculation tools [9]. For solving Maxwell's equations depending on the time, FDTD algorithm divides the space and time in a regular grid. Perfect matched layers (PMLs) can be used in the determination of the boundary conditions [10]. In general, the thickness of PML layer in overall simulation area is equal to a lattice constant. FDTD solves electric and magnetic fields by rating depending on space and time and deploys that rating in different spatial regions by sliding each field component half of a pixel. This procedure is known as Yee grid discretization. Fields in these grids can be classified as TM and TE polarization. In our calculations, we have used periodic boundary condition (PBC) and (PMLs) at x- and z-directions, respectively.

3 Result and discussion We calculate the spectral properties in the n-th order (n=10) Fibonacci-type quasiperiodic layered structures consisting of a $A^5B^6C^7$ compounds. The photonic band structures of 1D $A^5B^6C^7$ based PCs have been calculated in high-symmetry directions in the first Brillouin. The band structures with transmittance spectra for both photonic crystals are shown in Fig. 4 and Fig. 5. The calculated photonic band structures for both crystals are similar. The all pseudogaps exist in the frequencies where the effective refractive index of the structure is positive and the spectral width of the gaps is invariant with the change in the transmittance (see Tables 1 and 2). Figures 8 and 9 show the transmittivity of the structure containing a finite number (n=10) layers A and B arranged in the Fibonacci sequence. The positions of the minima in the transmission spectrum correlate with the gaps obtained in the calculation. A transmission spectrum of a 1D SbSI based PC is compared in Fig. 8 and Fig. 9 with a 1D SbSI based Fibonacci PC. One full period in spectrum which corresponds to the frequency range (0.2-0.5) (ωa/2πc) is presented. Although there is still a gap in the transmission spectrum of the Fibonacci structure around (0.2-0.5) (ωa/2πc), the spectrum is modified significantly. For the SbSeI based PC and Fibonacci PC the results we obtained are very close to the SbSI.

The numerical results of variation of full band gap with changing filling factor from 0.1 to 0.9 is given in Tables 1 and 2. Variation of band gap sizes is expressed as a percentage as a function of filling factor and is shown for TE mode in Fig. 5 and Fig. 6. In Fig. 5 and Fig. 6, it is clear that the size of the gap increases with filling factor for the first band gap. The largest gap size is about 38 % when the filling factor is as high as 0.4, but it decreases when the filling factor continues to increase. On the other hand, the fifth band gap size does not change too much according to filling factor, but it reaches the minimum value when filling factor is 0.7.

Table 2 Variation of full band gap size for TE modes with filling factor for anisotropic SbSeI based layers in air background.

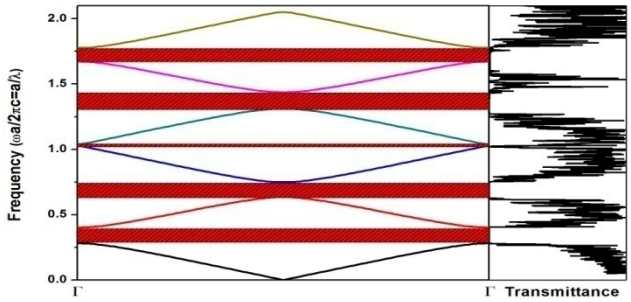

Figure 3 TE band structure and transmittance spectra of anisotropic SbSI.

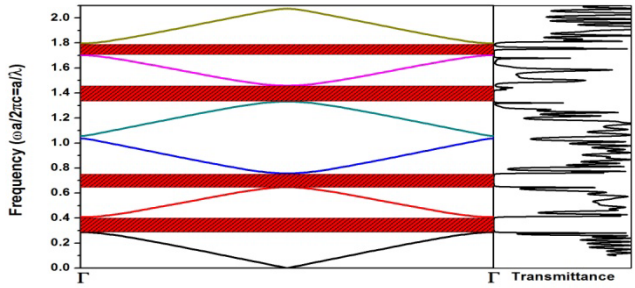

Figure 4 TE band structure and transmittance spectra of anisotropic SbSeI.

We also calculated the field distribution of the TE modes in our n-th (7) order Fibonacci sample, following a standard PWE method. The magnitude of the electric field (E) at the left interface of the dielectric layer is simply related to E at the right interface of the same layer by using matrix relation [11]. For 1D structures, it is also possible to compute the electric field distribution inside the sample (Fig. 7). The figure shows the normalized field intensity distribution for the wavelength of 1.55 μm on the n-th (n=7) interface.

4 Conclusion The photonic band structures and transmission properties of the 1D $A^5B^6C^7$ PCs consisting of dielectric layers immersed in air were studied. We have investigated transmittance spectra of $A^5B^6C^7$ based both normal PCs and Fibonacci PCs from 8 to 89 layers. The results show that the numbers of pseudo band gaps increase for Fibonacci PCs, when the numbers of the layers increase.
