RENORMALIZATIONS OF CIRCLE HOMEOMORPHISMS WITH A BREAK POINT*

AKHTAM DZHALILOV, ABDUMAJID BEGMATOV

ABSTRACT. Let \( f_\theta(x) = F_0(x) + \theta \pmod{1} \), \( x \in S^1 \), \( \theta \in [0, 1] \) be a family of preserving orientation circle homeomorphisms with a single break point \( x_b \), i.e. with a jump in the first derivative \( F_0' \) at the point \( x = x_b \). Suppose that \( F_0'(x) \) is absolutely continuous on \( [x_b, x_b + 1] \) and \( F_0''(x) \in L_\alpha([0, 1]) \) for some \( \alpha > 1 \). Consider \( f_\theta \) with rational rotation number \( \rho_\theta = \frac{p}{q} \) of rank \( n \), i.e. \( \frac{p}{q} = [k_1, k_2, \ldots, k_n] \). We prove that for sufficiently large \( n \), the renormalizations of \( f_\theta \) is close to certain convex linear-fractional functions in \( C^{1+L1} \).

Keywords: family of circle maps, break point, rotation number.

AMS Subject Classification: 37E10, 37C15, 37C40.

1. Introduction

Circle homeomorphisms constitute one important class of one-dimensional dynamical systems. The investigation of their properties was initiated by Poincaré [7], who came across them in his studies of differential equations more than a century ago. Since then interest in these maps never diminished. Circle maps are also important because of their applications to natural sciences (see for instance [2]).

We identify the unit circle \( S^1 = \mathbb{R}^1 / \mathbb{Z}^1 \) with the half open interval \( [0, 1) \). Consider the one-parameter families of the orientation preserving circle homeomorphisms

\[
    f_\theta(x) = F_0(x) + \theta \pmod{1}, \quad x \in S^1, \quad \theta \in [0; 1], \tag{1}
\]

where the initial lift \( F_0 : \mathbb{R}^1 \rightarrow \mathbb{R}^1 \) satisfies the following conditions:

(a) \( F_0 \) is continuous and strictly increasing on \( \mathbb{R}^1 \);

(b) \( F_0(0) = 0 \), \( F_0(x+1) = F_0(x) + 1 \), \( x \in \mathbb{R}^1 \);

(c) there is a point \( x_b \in S^1 \) such that the one-sided derivatives \( F_0'(x_b \pm 0) \) exist, are positive and \( F_0'(x_b - 0) \neq F_0'(x_b + 0) \);

(d) \( F_0' \) is absolutely continuous and strictly positive on \( [x_b, x_b + 1] \);

(e) \( F_0'' \in L^\alpha([0; 1], d\ell) \) for some \( \alpha > 1 \), where \( \ell \) is Lebesque measure on the circle.

The conditions (d) and (e) are called the Katznelson and Ornstein's smoothness conditions. The point \( x_b \) is called a break point of \( f_\theta \). The ratio

\[
    \sigma(x_b) = \sqrt{\frac{F_0'(x_b - 0)}{F_0'(x_b + 0)}}
\]

is called the jump ratio of \( f_\theta \) at \( x_b \) or, for short, \( f_\theta \)-jump ratio. Notice that the parameter \( \sigma = \sigma(x_b) \) is obviously an invariant under smooth coordinate transformations and characterizes the type of the singularity.

Put \( F_\theta = F_0 + \theta, \theta \in [0,1] \). The rotation number \( \rho_\theta \) of \( f_\theta \) is defined by (see [1] for details)

\[
\rho_\theta = \lim_{n \to \infty} \frac{F_\theta^n(x)}{n} \pmod{1},
\]

where the limit exists for all \( x \in \mathbb{R}^1 \) and is independent of \( x \). Here and later, \( F^n \) denotes the \( n - \text{th} \) iteration of \( F \).

The families like

\[
A_\theta(x) = x + \frac{c}{2\pi} \sin(2\pi x) + \theta \pmod{1}
\]

were studied for various constants \( c \). For \( c < 1 \) the maps are diffeomorphisms and there is a result in [3], which says that the rotation number is absolutely continuous as a function of \( \theta \). When \( c > 1 \) the maps are non homeomorphisms and have no rotation number. In this case, both endpoints of rotation interval are rational almost everywhere w.r.t Lebesgue measure. Notice that the results are quite different if the family (1) has singularity points. Swiatek in [8] studied the family (1) with several critical points. It is proved that the set of parameter values corresponding to irrational rotation numbers has Lebesgue measure zero. In other words, the intervals on which frequency-locking occurs fill up the set of full measure. Khanin and Vul in [6] studied the family (1) with a single point, but with a weaker smoothness condition for \( f \).

It is easy to see that \( \rho_\theta \) is the increasing function of \( \theta \). Note that for each rational number \( a \) the set \( I(a) = \{ \theta : \rho_\theta = a \} \) is a nontrivial closed interval and \( I(a) \) consists of only one point if \( a \) is irrational.

The main idea of the renormalization group method is to study large time iterates of the original mappings in a rescaled coordinate system corresponding to some neighborhood of a given point. Let \( \frac{p}{q} \in [0,1] \) be an arbitrary rational number of rank \( n \), i.e. \( \frac{p}{q} = [k_1, k_2, ..., k_n] \), \( k_n > 1 \). Since the rank of \( \frac{p}{q} \) equals \( n \) we put \( p_n := p \) and \( q_n := q \). Let us fix some \( \theta \in I(\frac{p_n}{q_n}) \) and denote \( F = F_\theta \) and \( f = f_\theta \) (we omit the parameter \( \theta \) in the sequel). Let \( O_f(t,q_n) = \{ f^i(t), i = 0, 1, ..., q_n - 1 \} \) be an arbitrary periodic orbit of \( f \) of period \( q_n \). Denote by \( [y_1, y_2] \) the closed interval formed by two consecutive points of orbit \( O_f(t,q_n) \) and containing the break point \( x_b \) of \( f \). We introduce the renormalized coordinate \( z \) on \( [y_1, y_2] \) given by the formula \( z = (x - y_2)/(y_1 - y_2) \). It is clear that the normalized coordinate \( z \) changes from 1 to 0, when \( x \) is moving from \( y_1 \) to \( y_2 \). Denote by \( d \) the renormalized coordinate of break point \( x_b \), i.e. \( d = (x_b - y_2)/(y_1 - y_2) \).

Now, we define the function \( \tilde{f}_{\rho,n} \) corresponding to \( F^{q_n} \) in this new coordinate by:

\[
\tilde{f}_{\rho,n}(z) = \frac{F^{q_n}(y_2 + z(y_1 - y_2)) - y_2 - p_n}{y_1 - y_2}, \quad z \in [0,1].
\]
The least map is called \( n - \text{th renormalization of } f \) on the interval \([y_1, y_2]\). Next, we define the piecewise fractional-linear function \( G_{d,n} \) on \([0,1]\) by the formula:

\[
G_{d,n}(z) = \begin{cases} 
\frac{\sigma^n z + d(1-\sigma^n)}{\sigma^n z + d(1-\sigma^n)}, & \text{if } z \in [0,d], \\
\frac{\sigma^n z + d(1-\sigma^n)}{\sigma^n z + d(1-\sigma^n)}, & \text{if } z \in (d,1].
\end{cases}
\]

(3)

The main purpose of our paper is to prove the following:

**Theorem 1.1.** Let \( \{f_\theta : \theta \in [0,1]\} \) be the family of circle homeomorphisms defined by (1) with the initial lift \( F_0 \) satisfying the conditions (a)-(e). Then, for any \( \varepsilon > 0 \) there exists \( N = N(\varepsilon, F_0) > 0 \) (which doesn’t depend on choice of periodic orbit), such that if \( f \) belongs to this family and its rotation number \( \rho = \frac{p_n}{q_n} \) is rational with rank \( n, n > N \) the following estimates hold:

\[
\|\hat{f}_{p,n} - G_d\|_{C([0,1])} \leq \varepsilon, \quad \|\hat{f}_{p,n}^m - G_d^m\|_{L^1([0,1],dt)} \leq \varepsilon.
\]

**Remark 1.1.** Using the assertions of Theorem 1.1 it can easily be shown that

\[
\sup_{z \in [0,1] \setminus \{d\}} |\hat{f}_{p,n}^m - G_d^m| \leq \varepsilon.
\]

2. **Dynamical partitions of circle homeomorphisms with rational rotation number**

Let \( f \) be an orientation preserving homeomorphism of the circle with rational rotation number \( \rho = \frac{p_n}{q_n} = [k_1, k_2, ..., k_n] \). For \( 1 \leq m \leq n \) denote by \( \frac{p_n}{q_n} = [k_1, k_2, ..., k_m] \), the convergent of \( \frac{p_n}{q_n} \). Their denominators \( q_m \) satisfy \( q_{m+1} = k_{m+1}q_m + q_{m-1}, 1 \leq m \leq n - 1, q_0 = 1, q_1 = k_1 \). Since the rotation number \( \rho = \frac{p_n}{q_n} \) is rational homeomorphism \( f \) has at least one periodic orbit of period \( q_n \) (see [1]). Let \( O_f(t, q_n) = \{f^i(t), i = 0, 1, ..., q_n - 1\} \) be a periodic orbit of \( f \) of period \( q_n \). For an arbitrary point \( x_0 \in O_f(t, q_n) \), denote by \( \Delta_{(0)}(x_0) \) the closed interval with endpoints \( x_0 \) and \( x_{q_n} = f^{q_n}x_0, 0 \leq m \leq n - 1 \). If \( m \) is odd then \( x_{q_n} \) is to the left of \( x_0 \), and to the right of \( x_0 \) if \( m \) is even. Denote by \( \Delta_{(m)}(x_0) \) the iterates of the interval \( \Delta_{(0)}(x_0) \) under \( f \):

\[
\Delta_{(m)}(x_0) = f^i\Delta_{(0)}(x_0), i \geq 1, 0 \leq m \leq n - 1.
\]

It is well known that each of the following system of intervals

\[
\xi_m(x_0) = \left\{ \Delta_{(m-1)}(x_0), 0 \leq i < q_m; \Delta_{(m)}(x_0), 0 \leq j < q_{m-1} \right\}, 1 \leq m < n,
\]

\[
\xi_n(x_0) = \left\{ \Delta_{(n-1)}(x_0), 0 \leq i < q_n \right\}
\]

cover the whole circle and that their interiors are mutually disjoint. The partition \( \xi_m(x_0) \) is called the \( m \text{th dynamical partition of the point } x_0 \). We briefly recall the structure of the dynamical partitions. The passage from \( \xi_m(x_0) \) to \( \xi_{m+1}(x_0), 1 \leq m < n - 2 \) is simple: namely, all intervals of rank \( m \) are preserved and each of the intervals \( \Delta_{(m-1)}(x_0) \), \( 0 \leq i < q_m \), is divided into \( (k_{m+1} + 1) \) intervals: \( \Delta_{(m-1)}(x_0) = \Delta_{(m)}(x_0) \cup \bigcup_{s=0}^{k_{m+1}-1} \Delta_{(m)}(x_0) \). Note that the endpoints of intervals \( \Delta_{(n-1)}(x_0), 0 \leq i < q_n - 1 \) are periodic points of \( f \) of period \( q_n \). Also each interval of partition \( \xi_n(x_0) \) is periodic of period \( q_n \). The following lemma plays a key role for studying metrical properties of the homeomorphism \( f \).

**Lemma 2.1.** Let \( f \) be a circle homeomorphism with lift \( F \) and rational rotation number \( \rho_f = \frac{p_n}{q_n} \) of rank \( n \). Let the finite derivatives \( F'(x_b \pm 0) > 0 \) exist and let \( F \in C^1([x_b, x_b + 1]) \) and \( \text{var}_{[x_b, x_b + 1]} \log F' = \bar{v} < \infty \). We write

\[
v = \bar{v} + | \log F'(x_b - 0) - \log F'(x_b + 0) | = \bar{v} + 2 \log \sigma(x_b).
\]
It is clear that \( \Delta \subset \Delta(x) \in \xi(x), \Delta(k) \in \xi(k(x)), 1 \leq l < k \leq n. \) Then the functions \( \lambda \) holds for any \( 1 \leq k \leq n \) and \( x_0 \in S^1 \) such that \( x_i \neq x_k, i = 0, 1, 2, ..., n. \)

The last inequality is called the Denjoy inequality. The proof of Lemma 2.1 is just like that of the similar assertion for diffeomorphism (see for instance [5]). Using Lemma 2.1 it can easily be shown that the lengths of the intervals of the dynamical partition \( \xi_n \) are exponentially small.

**Corollary 2.1.** Suppose that \( \Delta(k) \subset \Delta \in \xi(x), \Delta(k) \in \xi(k(x)), 1 \leq l < k \leq n. \) Then for some constant \( M_0 > 0 \)

\[
I(\Delta(k)) \leq M_0 \lambda^{k-1}I(\Delta(l)),
\]

where \( \lambda = (1 + e^{-2\nu})^{-1/2} < 1. \)

3. Proof of Theorem 1.1

Consider the dynamical partition generated by periodic orbit \( O_f(t, q_n) \). By assumption \([y_1, y_2]\) is the closed interval formed by two consecutive points of \( O_f(t, q_n) \) and containing the break point \( x_k \). We put \( x_0 = y_1 \). Consider the partition \( \xi_n(x_0) \). It is clear that \( \Delta(0^{(n-1)}(x_0)) \) and \( f_{q_n}\Delta_0^{(n-1)}(x_0) = \Delta_0^{(n-1)}(x_0) \). It follows from Corollary 2.1, that the intervals of the dynamical partition \( \xi_n(x_0) \) have exponentially small length, i.e. \( \ell(\Delta_0^{(n-1)}(x_0)) \leq const \lambda^n, \lambda \in (0, 1). \)

Note that the function \( f_\rho, n(z) \) can be represented as the superposition of two functions, \( \bar{f}_1 \) and \( \bar{f}_2 \), which correspond to the mappings \( f : \Delta_0^{(n-1)}(x_0) \rightarrow \Delta_1^{(n-1)}(x_0), f_{q_n}^{(n-1)} : \Delta_1^{(n-1)}(x_0) \rightarrow \Delta_0^{(n-1)}(x_0) \), respectively. We introduce relative coordinates \( z_i, i = 0, 1, ..., q_n-1 \), in the intervals \( \Delta_1^{(n-1)}(x_0) \)

\[
z_i = (f^i(x) - f^i(y_2))/(f^i(y_1) - f^i(y_2)), \quad x \in \Delta_0^{(n-1)}(x_0).
\]

Then the functions \( \bar{f}_1 \) and \( \bar{f}_2 \) can be written as

\[
\bar{f}_1(z_0) = \frac{f(y_2 + (y_1 - y_2)z_0) - f(y_2)}{f(y_1) - f(y_2)},
\]

\[
\bar{f}_2(z_1) = \frac{f_{q_n}^{(n-1)}(y_2) + (f(y_1) - f(y_2))z_1 - y_2}{y_1 - y_2}.
\]

It is clear that \( \bar{f}_{\rho, n}(z) = \bar{f}_2(\bar{f}_1(z)) \). Define the following functions:

\[
g(z_1) = \frac{\sigma z_1}{1 + z_1(\sigma - 1)}, \quad R_d(z_0) = \begin{cases} \sigma z_0, & \text{if } z_0 \in [0, d], \\ \sigma^2 z_0 + d(1 - \sigma^2), & \text{if } z_0 \in (d, 1].
\end{cases}
\]

We put \( M_n = \exp\{\sum_{i=1}^{q_n-2} \int_{\Delta_1^{(n-1)}} \frac{f'(y)}{f(y)} dy\} \). From now on we shall denote by \( K \) constants that depend only on the original family \( f_\rho \). Next, we formulate two necessary lemmas.

**Lemma 3.1.** For any \( \varepsilon > 0 \), the following relation holds for sufficiently large \( n \)

\[
z_{q_n-1}(z_1) = \frac{z_1 M_n \exp(\tau_n(z_1))}{1 + z_1(\bar{M}_n \exp(\tau_n(z_1) - 1))},
\]

where the function \( \tau_n(z_1) \) and its derivatives satisfies the following inequalities:

\[
\max_{0 \leq z_1 \leq 1} |\tau_n(z_1)| \leq \varepsilon, \quad \max_{0 \leq z_1 \leq 1} \left| (z_1 - z_1^2)\tau_n'(z_1) \right| \leq \varepsilon,
\]
by definition

\[ \| \tau'_n(z_1) \|_{L^1([0,1], dt)} \leq \varepsilon, \quad \| (z_1 - z_1^2) \tau''_n(z_1) \|_{L^1([0,1], dt)} \leq \varepsilon. \]  \hfill (11)

**Lemma 3.2.** The following estimates hold for sufficiently large \( n \)

\[ \| f_1 - R_d \|_{C((0,1])} \leq K \lambda^{3 \beta}, \quad \| \bar{f}'_1 - R'_d \|_{L^1([0,1], dt)} \leq K \lambda^{3 \beta}, \]  \hfill (12)

where \( \lambda \) is the same as in Corollary 2.1 and \( \beta = \frac{\alpha}{\alpha - 1} \).

For an easy flow of our presentation, we shall prove these two Lemmas at the end of this section. So we continue our proof of Theorem 1.1. It is not hard to show that \( f_2(z_1) = z_{q_n - 1}(z_1) \).

Using the last relation and Lemma 3.1, we obtain

\[ \| \bar{f}_2(z_1) - \frac{M_n z_1}{1 + z_1(M_n - 1)} \|_{C^1([0,1])} \leq \varepsilon, \]  \hfill (13)

\[ \| \bar{f}''_2(z_1) - \frac{2M_n(1 - M_n)}{(1 + z_1(M_n - 1))^3} \|_{L^1([0,1], dt)} \leq \varepsilon. \]  \hfill (14)

It is clear that

\[ \ln M_n = \sum_{i=1}^{q_n - 1} \int_{\Delta_{i,1}(x_0)} \frac{f''(y)}{2f'(y)} dy = \ln \sigma - \int_{\Delta_0^{(n-1)}(x_0)} \frac{f''(y)}{2f'(y)} dy - \int_{\Delta_{q_n-1}^{(n-1)}(x_0)} \frac{f''(y)}{2f'(y)} dy. \]  \hfill (15)

Thus, we have

\[ \left| \int_{\Delta_{i,1}^{(n-1)}(x_0)} \frac{f''(y)}{2f'(y)} dy \right| \leq K \| f'' \|_{L^1([0,1], dt)} \leq K \lambda^{\beta n}, \quad \text{for, } k = 0, q_n - 1. \]

Together with relations (13)-(15) this implies that

\[ \| \bar{f}_2 - g \|_{C^1([0,1])} \leq \varepsilon, \quad \| \bar{f}''_2 - g'' \|_{L^1([0,1], dt)} \leq \varepsilon. \]

So, the relation \( f_{\rho, n}(z) = \bar{f}_2(f_1(z)) \) and Lemma 3.2 imply the proof of Theorem 1.1.

**Proof.** Lemma 3.1. Denote \( a_i = f^i(y_1), \quad b_i = f^i(y_2), \quad x_i = f^i(x), \) \( i = 1, 2, ..., q_n - 1 \). Then we get

\[ z_{i+1} = (x_{i+1} - b_{i+1})/(a_{i+1} - b_{i+1}). \]  \hfill (16)

It is easy to check that

\[ x_{i+1} = f(x_i) = f(a_i) + f'(a_i)(x_i - a_i) + \int_{a_i}^{x_i} f''(y)(x_i - y) dy, \]

\[ b_{i+1} = f(b_i) = f(a_i) + f'(a_i)(b_i - a_i) + \int_{a_i}^{b_i} f''(y)(b_i - y) dy, \]

by definition \( a_{i+1} = f(a_i) \). Substituting this into (16) we get

\[ z_{i+1} = z_i(1 + A_i(z_i - 1)), \quad i = 1, 2, ..., q_n - 1, \]  \hfill (17)

where

\[ A_i = -\frac{\int_{a_i}^{x_i} f''(y)(y - a_i) dy + \int_{b_i}^{x_i} f''(y)(y - b_i) dy}{\int_{a_i}^{x_i} f''(y)(x_i - y) dy + \int_{b_i}^{x_i} f''(y)(b_i - y) dy}. \]  \hfill (18)
We denote
\[ \tau_n(z_1) = \sum_{i=1}^{q_n-2} \psi_i, \]
where
\[ \chi_i = \int_{a_i}^{b_i} \frac{f''(y)}{2f'(y)} dy, \quad \psi_i = -\chi_i - \ln \left( \frac{1 + A_i z_i}{1 + A_i(z_i - 1)} \right), \quad i = 1, 2, \ldots, q_n - 1. \]

Using (17) we obtain
\[ \frac{1 - z_{i+1}}{z_{i+1}} = \frac{1 - z_i}{z_i} \frac{1 + A_i z_i}{1 + A_i(z_i - 1)} = \frac{1 - z_i}{z_i} \exp\{-\chi_i\} \exp\{-\psi_i\}. \tag{19} \]

Taking iteration of (19) we get
\[ \frac{1 - z_{q_n-1}}{z_{q_n-1}} = \frac{1 - z_1}{z_1} \exp\{-\sum_{i=1}^{q_n-2} \chi_i\} \exp\{-\sum_{i=1}^{q_n-2} \psi_i\} = \frac{1 - z_1}{z_1} M_n \exp \tau_n(z_1). \tag{20} \]

Solving equation (20) with respect to \( z_{q_n-1} \) we obtain the relation (9).

Let us estimate \( \tau_n(z_1) \). First we estimate \( A_i \). Denote by \( V_i \) the second term of the denominator of (18). Since \( f''(x) \in L_\alpha([0, 1], d\ell) \) applying the Holder inequality we obtain
\[ |V_i| \leq \frac{1}{f'(a_i)(b_i - a_i)} \int_{a_i}^{b_i} \big| f''(y) \big| (y - a_i) dy \leq \|f''\|_\alpha (b_i - a_i)^{1+\frac{\beta}{2}} (1 + \beta) \leq K(b_i - a_i)^{\frac{\beta}{2}}. \tag{21} \]

Analogously, it can be shown that the absolute values of both terms in (18) are not greater than \( K(b_i - a_i)^{\frac{\beta}{2}} \). Let us recall that \([a_i, b_i] \in \xi_n(x_0)\) and \( \ell([a_i, b_i]) \leq K\lambda^n, \quad i = 0, 1, \ldots, q_n - 2 \). This, together with the expression for \( A_i \), imply that \( |A_i| \leq \text{Const}\lambda^\frac{\beta}{2} \). Next, we rewrite \( \tau_n(z_1) \) in the form
\[ \tau_n(z_1) = -\sum_{i=1}^{q_n-2} \chi_i - \sum_{i=1}^{q_n-2} \ln \left( \frac{1 + A_i z_i}{1 + A_i(z_i - 1)} \right) = -\ln M_n - \sum_{i=1}^{q_n-2} A_i - \sum_{i=1}^{q_n-2} 0(A_i^2). \tag{22} \]

We estimate the last sum in (22). Note that each term of (18) containing an integral is not greater than \( \int_a^{b_i} f''(y) dy \). Using the estimate for \( A_i \), it can easily be shown that
\[ \sum_{i=1}^{q_n-2} O(A_i^2) \leq K\lambda^\frac{\beta}{2}. \tag{23} \]

We rewrite the second to the last sum in (22) in the following form
\[ \sum_{i=1}^{q_n-2} A_i = -\sum_{i=1}^{q_n-2} \int_{a_i}^{b_i} \frac{f''(y)}{2f'(y)} dy - \sum_{i=1}^{q_n-2} \left[ \frac{1}{f'(a_i)(x_i - a_i)} \int_{a_i}^{x_i} f''(y)(y - a_i) dy - \frac{1}{2} \int_{a_i}^{x_i} f''(y) dy \right] - \]
\[ - \sum_{i=1}^{q_n-2} \left[ \frac{1}{f'(a_i)(b_i - x_i)} \int_{x_i}^{b_i} f''(y)(b_i - y) dy - \frac{1}{2} \int_{x_i}^{b_i} f''(y) dy \right] + \sum_{i=1}^{q_n-2} \frac{V_i}{1 + V_i} \left[ \frac{1}{f'(a_i)(x_i - a_i)} \int_{a_i}^{x_i} f''(y)(y - a_i) dy + \frac{1}{f'(a_i)(b_i - x_i)} \int_{x_i}^{b_i} f''(y)(b_i - y) dy \right]. \tag{24} \]
The first after the sign of equality sum equals to \((-\ln M_n)\). Since \(|V_i| \leq K\lambda^\beta_n\), the last sum is not greater than \(K\lambda^\beta_n\). Together with relations (22)-(24), the last inequality implies that

\[
\tau_n(z_1) = -\sum_{i=1}^{q_n-2} \left[ \frac{1}{f'(a_i)} \left( \frac{x_i}{a_i} \right) \int_{a_i}^{x_i} f''(y)(y-a_i) dy - \frac{1}{2} \int_{a_i}^{x_i} f''(y) dy \right] - \frac{q_n-2}{2} \left( \frac{b_i}{x_i} \right) \int_{x_i}^{b_i} f''(y)(b_i-y) dy - \frac{1}{2} \int_{x_i}^{b_i} f''(y) dy \right] + O(\lambda^\beta_n).
\]

Denote by \(S_n\) and \(\bar{S}_n\) the last two sums in (25) respectively. Then, we show that for any \(\varepsilon > 0\), the following estimates hold for sufficiently large \(n\):

\[
|S_n|, \ |\bar{S}_n| \leq K\varepsilon.
\]

We prove only the estimate for \(S_n\), the one for \(\bar{S}_n\) is quite similar. Rewrite the sum \(S_n\) as

\[
S_n = \sum_{i=1}^{q_n-2} \int_{a_i}^{x_i} f''(y) \left( \frac{y-a_i}{x_i-a_i} - \frac{1}{2} \right) dy + \sum_{i=1}^{q_n-2} \int_{a_i}^{x_i} \left( \frac{f''(y)}{2f'(a_i)} \right) \left( \frac{y}{f'(a_i)} \right) \int_{a_i}^{x_i} f''(t) dt \right) dy \equiv S_n^{(1)} + S_n^{(2)}.
\]

Using the condition \(f''(x) \in L_\alpha(S^1, dl)\), \(\alpha > 1\), and the Hölder inequality, it can easily be shown that

\[
|S_n^{(2)}| \leq K \sum_{i=1}^{q_n-2} \left( \int_{a_i}^{x_i} |f''(y)| dy \right)^2 \leq K\lambda^\beta_n.
\]

Let us estimate the sum \(S_n^{(1)}\). Fix an arbitrary \(\varepsilon > 0\). Since \(f''(x) \in L_\alpha(S^1, dl)\), it can be written in the form

\[
f''(x) = h_\varepsilon(x) + r_\varepsilon(x), \ x \in S^1,
\]

where \(h_\varepsilon(x)\) is a continuous function on \(S^1\) and \(\|r_\varepsilon\|_{L_1} < \varepsilon\). Substituting (29) in expression for \(S_n^{(1)}\), we obtain

\[
|S_n^{(1)}| \leq \sum_{i=1}^{q_n-2} \int_{a_i}^{x_i} h_\varepsilon(y) \left( \frac{y-a_i}{x_i-a_i} - \frac{1}{2} \right) dy + \sum_{i=1}^{q_n-2} \int_{a_i}^{x_i} r_\varepsilon(y) \left( \frac{y-a_i}{x_i-a_i} - \frac{1}{2} \right) dy \equiv P_n + Q_n.
\]

First, we estimate the sum \(P_n\). Denote by \(t_i\) the middle of the interval \([a_i, x_i]\) i.e. \(t_i = \frac{x_i + a_i}{2}\). We rewrite the sum \(P_n\) in the following form

\[
P_n = \sum_{i=1}^{q_n-2} \int_{a_i}^{t_i} h_\varepsilon(y) \left( \frac{y-a_i}{x_i-a_i} - \frac{1}{2} \right) dy + \sum_{i=1}^{q_n-2} \int_{t_i}^{x_i} h_\varepsilon(y) \left( \frac{y-a_i}{x_i-a_i} - \frac{1}{2} \right) dy.
\]

Applying the Mean Value Theorem we obtain

\[
P_n = \sum_{i=1}^{q_n-2} h_\varepsilon(\xi_1) \left( \frac{y-a_i}{x_i-a_i} - \frac{1}{2} \right) dy + \sum_{i=1}^{q_n-2} h_\varepsilon(\xi_2) \left( \frac{y-a_i}{x_i-a_i} - \frac{1}{2} \right) dy =
\]

where \(\xi_1, \xi_2 \in (a_i, x_i)\).
= \sum_{i=1}^{q_n-2} \frac{x_i - a_i}{16 f'(a_i)} |h_\varepsilon(\xi_2^i) - h_\varepsilon(\xi_1^i)| \leq \sum_{i=1}^{q_n-2} \frac{x_i - a_i}{16 f'(a_i)} \omega(\lambda^n, h_\varepsilon, [a_i, b_i]) \leq K \max_{1 \leq i \leq q_n-2} \omega(\lambda^n, h_\varepsilon, [a_i, b_i]),

where \( \omega(\lambda^n, h_\varepsilon, [a_i, b_i]) = \sup |h_\varepsilon(\xi_2^i) - h_\varepsilon(\xi_1^i)| \) is the "modulus of continuity" of \( h_\varepsilon \). Since \( \lambda \in (0, 1) \), we have \( \omega(\lambda^n, h_\varepsilon) \to 0 \), as \( n \to \infty \). Next, we estimate the sum \( Q_n \). It is easy to see that

\[
Q_n \leq K \sum_{i=1}^{q_n-2} \int_{a_i}^{x_i} |r_\varepsilon(y)|dy \leq K \int_{S^1} |r_\varepsilon(y)|dy \leq K \varepsilon.
\]

Hence, the relations in (26) are proved. Then, summing (22)-(26), we obtain the first relation in (10).

Let us prove the second relation in (10). Note that there exists a constant \( C_2 > 0 \) such that the following inequalities hold for all \( i, i = 1, 2, ..., q_n - 2, \)

\[
\frac{1}{C_2} \leq \frac{z_1(1 - z_1)}{z_i(1 - z_i)} \leq C_2, \quad \frac{1}{C_2} \leq \frac{dz_i}{dz_1} \leq C_2.
\]

(32)

Notice that the function \( \frac{d\psi_i}{dz_i} \) is defined almost everywhere. Using (18), we calculate the derivative of \( \psi_i \) by \( z_i \):

\[
\frac{d\psi_i}{dz_i} = \frac{A_i^2 - A_i'}{(1 + A_i z_i)(1 + A_i(z_i - 1))},
\]

(33)

where

\[
A_i' = \frac{dA_i}{dz_i} = \frac{dA_i}{dx_i} \frac{dx_i}{dz_i} = (b_i - a_i) \frac{dA_i}{dx_i},
\]

\[
dA_i = \frac{1}{f'(a_i)(x_i - a_i)^2} \int_{a_i}^{x_i} f''(y)(y - a_i)dy - \frac{1}{f'(a_i)(b_i - x_i)} \int_{x_i}^{b_i} f''(y)(b_i - y)dy
\]

\[
+ \frac{1}{f'(a_i)(b_i - a_i)} \int_{a_i}^{x_i} f''(y)(b_i - y)dy.
\]

(34)

Using (23), (28), (32)-(34) we obtain

\[
|(z_1 - z_2^i)\tau'_n(z_1)| = \left|(z_1 - z_2^i) \sum_{i=1}^{q_n-2} \frac{d\psi_i}{dz_i} \frac{dz_i}{dz_1} \right| \leq
\]

\[
\leq K \sum_{i=1}^{q_n-2} (z_i - z_2^i)(b_i - a_i) \left[ \int_{a_i}^{x_i} h_\varepsilon(y) \frac{y - a_i}{(x_i - a_i)^2}dy - \int_{x_i}^{b_i} h_\varepsilon(y) \frac{b_i - y}{(b_i - x_i)^2}dy \right] + O(\lambda^{\frac{3}{2}}).
\]

(35)

Denote by \( E_n \) the last sum in (35). Using relation (29) we rewrite \( E_n \) in the following form

\[
E_n = \left[ \sum_{i=1}^{q_n-2} (z_i - z_2^i)(b_i - a_i) \left[ \int_{a_i}^{x_i} h_\varepsilon(y) \frac{y - a_i}{(x_i - a_i)^2}dy - \int_{x_i}^{b_i} h_\varepsilon(y) \frac{b_i - y}{(b_i - x_i)^2}dy \right] \right] +
\]

\[
+ \sum_{i=1}^{q_n-2} \left[ z_i \int_{a_i}^{x_i} r_\varepsilon(y) \frac{y - a_i}{x_i - a_i}dy - (1 - z_i) \int_{x_i}^{b_i} r_\varepsilon(y) \frac{b_i - y}{b_i - x_i}dy \right] \equiv E_n^{(1)} + E_n^{(2)}.
\]

First, we estimate the sum \( E_n^{(1)} \). Applying the Mean Value Theorem again we get

\[
E_n^{(1)} \leq K \sum_{i=1}^{q_n-2} (b_i - a_i)|h_\varepsilon(\xi_1^i) - h_\varepsilon(\xi_2^i)| \leq
\]

(37)
Denote by $K \sum_{i=1}^{q_n-2} (b_i - a_i) \omega(\lambda^n, h_\e) \leq K \max_{1 \leq i \leq q_n-2} \omega(\lambda^n, h_\e, [a_i, b_i])$.

Let us estimate $E_n^{(2)}$. It is easy to see that

$$E_n^{(2)} \leq \frac{1}{2} \sum_{i=1}^{q_n-2} \left[ \int_{a_i}^{x_i} |r_\e(y)| dy + \int_{x_i}^{b_i} |r_\e(y)| dy \right] \leq \frac{1}{2} \int_{x_i}^{b_i} |r_\e(y)| dy < \e.$$  

This, together with (35)-(37) imply the second relation in (10). Now, we prove the first relation in (11). Using the same arguments as in (35), we can show that

$$\int_{z_1}^{1} |r'_n(z_1)| dz_1 \leq K \sum_{i=1}^{q_n-2} |b_i - a_i| \int_{a_i}^{x_i} f''(y) \frac{y - a_i}{(x_i - a_i)^2} dy - \int_{x_i}^{b_i} f''(y) \frac{b_i - y}{(b_i - x_i)^2} dy \right| dz_1 + O(\lambda^n).$$

Using relations (32), it is easy to see that

$$\int_{z_1}^{1} |r''_n(z_1)| dz_1 \leq K \sum_{i=1}^{q_n-2} \int_{a_i}^{b_i} f''(y) \frac{y - a_i}{(x_i - a_i)^2} dy - \int_{x_i}^{b_i} f''(y) \frac{b_i - y}{(b_i - x_i)^2} dy \right| dx_i + O(\lambda^n).$$

We denote by $I_n$ the last sum in (39) and estimate it. Using the representation (29), we get

$$I_n \leq \sum_{i=1}^{q_n-2} \int_{a_i}^{b_i} \left[ \int_{a_i}^{x_i} h_\e(y) \frac{y - a_i}{(x_i - a_i)^2} dy - \int_{x_i}^{b_i} h_\e(y) \frac{b_i - y}{(b_i - x_i)^2} dy \right] dx_i + \sum_{i=1}^{q_n-2} \int_{a_i}^{b_i} \left[ \int_{x_i}^{b_i} r_\e(y) \frac{b_i - y}{(b_i - x_i)^2} dy \right] dx_i.$$  

It can easily be shown that the first sum in (40) is not greater than

$$\max_{1 \leq i \leq q_n-2} \omega(\lambda^n, h_\e, [a_i, b_i]).$$  

Denote by $I_n^{(1)}$ the second to the last sum in (40). Applying the Hölder inequality we obtain

$$I_n^{(1)} = \sum_{i=1}^{q_n-2} \int_{a_i}^{b_i} \frac{1}{(x_i - a_i)^{\frac{1}{2}}} \int_{a_i}^{x_i} r_\e(y)(y - a_i) dy \right| dx_i \leq K \sum_{i=1}^{q_n-2} \int_{x_i}^{b_i} \left( \int_{a_i}^{x_i} r_\e(y)^{\alpha} dy \right)^{\frac{1}{\alpha}} dx_i \leq K \sum_{i=1}^{q_n-2} \left( \int_{a_i}^{x_i} r_\e(y)^{\alpha} dy \right)^{\frac{1}{\alpha}} (b_i - a_i)^{\frac{1}{\beta}} \leq K \left( \sum_{i=1}^{q_n-2} \int_{a_i}^{b_i} r_\e(y)^{\alpha} dy \right)^{\frac{1}{\alpha}} \leq K \e^{\frac{1}{\alpha}}.$$
Analogously, it can be shown that the last sum in (40), is also not greater than $K\varepsilon^{1/2}$. Together with (38)-(41), this implies the first relation in (11).

Let us prove the second inequality in (11). It is not too hard to show that there exists a constant $C_3 > 0$ such that for all $i, 1 \leq i \leq q_n - 2$

$$ \frac{1}{C_3} \leq \int_0^1 |\frac{d^2 z_i}{dz_i^2}| dz_1 \leq C_3. \quad (42) $$

Note that the function $\frac{d^2 \psi_i}{dz_i^2}$ is defined almost everywhere. By differentiating (33) we get

$$ \frac{d^2 \psi_i}{dz_i^2} = \frac{2A_i A_i' - A_i''}{(1 + A_i z_i)(1 + A_i(z_i - 1))} - \frac{2(A_i' z_i + a_i)}{1 + A_i z_i} \cdot \frac{d \psi_i}{dz_i} - \left( \frac{d \psi_i}{dz_i} \right)^2, \quad (43) $$

where

$$ A_i'' = \frac{d^2 A_i}{dz_i^2} = (b_i - a_i)^2 \frac{d^2 A_i}{dx_i^2}. \quad (44) $$

Finally, differentiating (34) gives

$$ \frac{d^2 A_i}{dx_i^2} = \frac{2}{f'(a_i)(x_i - a_i)^2} \int_{a_i}^{x_i} (f''(x_i) - f''(y))(y - a_i)dy + \frac{2}{f'(a_i)(b_i - a_i)^2} \int_{a_i}^{b_i} (f''(x_i) - f''(y))(b_i - y)dy $$

$$ \cdot \frac{1}{1 + \frac{1}{f'(a_i)(b_i - a_i)}} \int_{a_i}^{b_i} f''(y)(y - a_i)dy $$

$$ \quad (45) $$

Using the relations (10), (11), (43) and (45) it can easily be shown that

$$ \int_0^1 |(z_1 - z_1^2)\tau''(z_1)| dz_1 = \int_0^1 |(z_1 - z_1^2)\sum_{i=1}^{q_n-2} \left[ \frac{d^2 \psi_i}{dz_i^2} \left( \frac{d z_i}{dz_1} \right)^2 + \frac{d \psi_i}{dz_i} \frac{d^2 z_i}{dz_1^2} \right]| dz_1 \leq $$

$$ \leq K \int_0^1 |(z_1 - z_1^2)\sum_{i=1}^{q_n-2} (b_i - a_i)^2 \frac{d^2 A_i}{dx_i^2}| + K\varepsilon \leq $$

$$ \leq K \int_0^1 |(z_1 - z_1^2)\sum_{i=1}^{q_n-2} \left( \frac{b_i - a_i}{x_i - a_i} \right)^2 \int_{a_i}^{x_i} \left[ f''(x_i) - f''(y) \right] \frac{y - a_i}{x_i - a_i}dy | dz_1 + $$

$$ + K \int_0^1 |(z_1 - z_1^2)\sum_{i=1}^{q_n-2} \left( \frac{b_i - a_i}{x_i - a_i} \right)^2 \int_{a_i}^{b_i} \left[ f''(x_i) - f''(y) \right] \frac{b_i - y}{b_i - x_i}dy | dz_1 + K\varepsilon. $$

The proof of the second relation in (11) proceeds now exactly as in the previous case. This concludes the proof of Lemma 3.1. \qed

**Proof.** Lemma 3.2. It is easy to check, that

$$ f(x) - f(y_2) = f'(x_b + 0)(x - y_2) + \int_x^{y_2} f''(y)(y - y_2)dy, \quad x_b < x < y_2, $$

$$ f(x) - f(x_b) = f'(x_b - 0)(x - x_b) + \int_x^{x_b} f''(y)(y - x_b)dy, \quad y_1 < x < x_b.
\[f(y_1) - f(x_b) = f'(x_b - 0)(y_1 - x_b) + \int_{y_1}^{x_b} f''(y)(y - x_b)dy,\]

\[f(x_b) - f(y_2) = f'(x_b + 0)(x_b - y_2) + \int_{x_b}^{y_2} f''(y)(y - y_2)dy.\]

This together with (6) imply that

\[\tilde{f}_1(z_0) = \begin{cases} \frac{z_0 + H_1(x)}{\sigma^2(1 - d) + d + H_3 + H_4}, & z_0 \in [0, d], \\ \frac{\sigma^2 z_0 + d(1 - \sigma^2) + H_2(x) + H_4}{\sigma^2(1 - d) + d + H_3 + H_4}, & z_0 \in (d, 1], \end{cases} \tag{46}\]

where

\[H_1(x) = \frac{1}{f'(x_b + 0)(y_1 - y_2)} \int_{x}^{y_2} f''(y)(y - y_2)dy, \quad x \in [x_b, y_2],\]

\[H_2(x) = \frac{1}{f'(x_b + 0)(y_1 - y_2)} \int_{x_1}^{x_b} f''(y)(y - x_b)dy, \quad x \in [y_1, x_b],\]

\[H_3 = \frac{1}{f'(x_b + 0)(y_1 - y_2)} \int_{y_1}^{x_b} f''(y)(y - x_b)dy, \quad H_4 = \frac{1}{f'(x_b + 0)(y_1 - y_2)} \int_{x_b}^{y_2} f''(y)(y - y_2)dy.\]

Because \(\ell(\Delta_0^{(n-1)}) \leq \lambda^n\), using the condition (d) and Hölder inequality we find that the relation

\[|H_1(x)| \leq \frac{1}{f'(x_b + 0)(y_1 - y_2)} \int_{x}^{y_2} |f''(y)(y - y_2)|dy \leq K\lambda^{\frac{n}{2}} \tag{47}\]

holds for all \(x \in [y_1, x_b]\). Analogously, it can be shown that the following inequalities

\[|H_2(x)|, |H_3|, |H_4| \leq K\lambda^{\frac{n}{2}} \tag{48}\]

for all \(x \in (x_b, y_2]\). Summing (46)-(48), we get the first relation in (12). We have

\[\tilde{f}''_1(z_0) = \frac{f''(y_2 + z_0(y_1 - y_2))(y_1 - y_2)^2}{f(y_1) - f(y_2)} = \frac{1}{f'(x_b + 0)} \int_{x_b}^{y_2} f''(y_2 + z_0(y_1 - y_2))(y_1 - y_2)dy,\]

for almost all \(z_0\). Since the inequalities

\[\int_{0}^{d} |F'_1(z_0)|dz_0, \quad \int_{0}^{d} |F''_1(z_0)|dz_0 \leq K\lambda^{\frac{n}{2}}\]

hold, also in the case (47) this proves the second relation in (12). Lemma 3.2 is completely proved. \(\square\)
